LIMITING EIGENVALUE BEHAVIOR OF A CLASS OF LARGE DIMENSIONAL RANDOM MATRICES FORMED FROM A HADAMARD PRODUCT

JACK W. SILVERSTEIN

Abstract. This paper investigates the strong limiting behavior of the eigenvalues of the class of matrices \( \frac{1}{N}(D_n \circ X_n)(D_n \circ X_n)^* \), studied in Girko 2001. Here, \( X_n = (x_{ij}) \) is an \( n \times N \) random matrix consisting of independent complex standardized random variables, \( D_n = (d_{ij}) \), \( n \times N \), has nonnegative entries, and \( \circ \) denotes Hadamard (componentwise) product. Results are obtained under assumptions on the entries of \( X_n \) and \( D_n \) which are different from those in Girko (2001), which include a Lindeberg condition on the entries of \( D_n \circ X_n \), as well as a bound on the average of the rows and columns of \( D_n \circ D_n \). The present paper separates the assumptions needed on \( X_n \) and \( D_n \). It assumes a Lindeberg condition on the entries of \( X_n \), along with a tightness-like condition on the entries of \( D_n \).

1. Introduction

This paper deals with the limiting eigenvalue behavior of the class of Hermitian nonnegative definite matrices

\[
B_n = \frac{1}{N}(D_n \circ X_n)(D_n \circ X_n)^*,
\]

where for each positive integer \( n \) \( X_n = (x_{ij}^{(n)}) \) is \( n \times N \) with random variables \( x_{ij}^{(n)} \in \mathbb{C} \), independent, and standardized \( \mathbb{E}x_{ij}^{(n)} = 0, \mathbb{E}|x_{ij}^{(n)}|^2 = 1 \), \( D_n \) is \( n \times N \) containing nonrandom, nonnegative real numbers \( d_{ij} = d_{ij}^{(n)} \), \( \circ \) denotes Hadamard product, and \( N = N(n) \) with \( 0 < \lim \inf_n n/N \leq \lim \sup_n n/N < \infty \). Such matrices arise in various situations when the dimension is large and where there is no prescribed structure to the elements in the \( D_n \) matrix.

A standard way to pursue the limiting eigenvalue behavior of Hermitian random matrices as the dimension increases is through the empirical distribution function (e.d.f) of their eigenvalues, that is, for random Hermitian \( n \times n \) matrix \( A_n \), let for every \( x \in \mathbb{R} \), \( F_{A_n}(x) = \{ \text{number of eigenvalues of } A_n \leq x \}/n \). A standard tool used in understanding the (e.d.f) of the eigenvalues has been since Marčenko Pastur (1967), the Stieltjes transform, where for arbitrary finite measure \( \mu \) on \( \mathbb{R} \) is defined by

\[
m_\mu = \int_\mathbb{C}^+ \frac{1}{x-z}d\mu(x), \quad z \in \mathbb{C}^+ \equiv \{ z \in \mathbb{C} : \Im z > 0 \}.
\]

2010 Mathematics Subject Classification. Primary 15A18; 60F15; Secondary 62H99.

Key words and phrases. Eigenvalues of random matrices, Hadamard product, Deterministic equivalent.
It is analytic and takes values in $\mathbb{C}^+$. Notice that $m_\mu(z) \leq \mu(\mathbb{R})/3z$. The Stieltjes transform of the measure induced by $F_{A_n}$ is then
\[
m_{A_n} = \int \frac{1}{x - z} dF_{A_n}(x) = \frac{1}{n} \text{tr} (A_n - zI)^{-1},
\]
where $I$ is the $n \times n$ identity matrix, and $\text{tr}$ is the trace of a matrix.

Due to the inversion formula
\[
\mu([a, b]) = \frac{1}{\pi} \lim_{\eta \to 0^+} \int_a^b \Im m_\mu(\xi + i\eta) d\xi \quad (a, b \text{ continuity points of } \mu),
\]
it will follow that understanding the limiting behavior of $F_{A_n}$ can be handled by its Stieltjes transform.

Work on the eigenvalue behavior of $B_n$ has been done in [Girko 2001]. Indeed, Theorem 10.1 of [Girko 2001], contains the following result: assume $x_{ij}^{(n)} \in \mathbb{R},$
\[
\sup_n \max_{i=1, \ldots, n} \left\{ \frac{1}{n} \sum_{i=1}^N d_{ij}^2 + \frac{1}{N} \sum_{j=1}^N d_{ij}^2 \right\} < \infty,
\]
and a Lindeberg condition is satisfied, namely for arbitrary $\eta > 0$
\[
\lim_{n \to \infty} \max_{i=1, \ldots, n} \left\{ \frac{1}{n} \sum_{i=1}^n d_{ij}^2 E((x_{ij}^{(n)})^2 I(d_{ij} | x_{ij}^{(n)} | > \eta \sqrt{n})) + \frac{1}{N} \sum_{j=1}^N d_{ij}^2 E((x_{ij}^{(n)})^2 I(d_{ij} | x_{ij}^{(n)} | > \eta \sqrt{n})) \right\} = 0,
\]
where $I(A)$ is the indicator function on the set $A$. Then, with $\| \cdot \|$ denoting the sup norm on functions, for each $n$, there exists a nonrandom probability distribution function $F_0^n$, such that, with probability one
\[
\lim_{n \to \infty} \| F_{B_n} - F_0^n \| = 0.
\]
and $F_0^n$ has Stieltjes transform
\[
G_n(z) := \frac{1}{n} \sum_{i=1}^n \frac{1}{\sum_{k=1}^N d_{ik}^2 \frac{1}{1 + \frac{d_{ik}^2}{\gamma_k(z)}} - z},
\]
where for each $z \in \mathbb{C}^+$, $\gamma_1^0, \ldots, \gamma_N^0$ are unique solutions lying in $\mathbb{C}^+$ to the system of equations
\[
\gamma_j^0(z) = \frac{1}{n} \sum_{i=1}^n \frac{d_{ij}^2 \frac{1}{1 + \frac{d_{ij}^2}{\gamma_j(z)}} - z}{\sum_{k=1}^N d_{ij}^2 \frac{1}{1 + \frac{d_{ij}^2}{\gamma_k(z)}} - z}.
\]

This result is among a collection which differs from typical results on limiting eigenvalue behavior (as the dimension of the matrix increases), in that there is no statement on what a possible limiting e.d.f of the eigenvalues of $B_n$ could be. However, the result is important in that it shows that $F_{B_n}$ is becoming less random, with a way for deriving, through (1.3), what it is close to. The $F_0^n$'s can be thought of as deterministic equivalents of the e.d.f.'s
The aim of the current paper is to prove a result under different assumptions, in particular, for each \( \eta > 0 \)

\[
(1.7) \quad \lim_{n \to \infty} \frac{1}{nN} \sum_{jk} \mathbb{E}|x_{jk}^{(n)}|^2 I(|x_{jk}^{(n)}| \geq \eta \sqrt{n}) = 0,
\]

From this it is straightforward to construct a sequence \( \{\eta_n\} \) of positive numbers for which \( \eta_n \downarrow 0 \) as \( n \to \infty \) and

\[
(1.8) \quad \lim_{n \to \infty} \frac{1}{\eta_n^2 nN} \sum_{jk} \mathbb{E}|x_{jk}^{(n)}|^2 I(|x_{jk}^{(n)}| \geq \eta_n \sqrt{n}) = 0.
\]

We also assume the existence of positive \( e \) and \( f \) such that for all \( n \) sufficiently large

\[
(1.9) \quad e < \eta_n \sqrt{n} \quad \text{and} \quad \mathbb{E}|x_{jk}^{(n)} f(|x_{jk}^{(n)}| \leq e) - \mathbb{E}(x_{jk}^{(n)} I(|x_{jk}^{(n)}| \leq e))|^2 > f.
\]

Also, we assume each column of \( D_n \) is nonzero, and the matrix satisfies the following property. For every \( \epsilon > 0 \) there exists an \( M_\epsilon > 0 \) such that for each \( n \) there exists sets \( E_{re}^n \subset \{1, 2, \ldots, n\} \), \( E_{ce}^n \subset \{1, 2, \ldots, N\} \) such that

1. \( \#E_{re}^n + \#E_{ce}^n \leq cn \) (\( \# \) denotes number of elements in the set)
2. \( d_{jk}^n \leq M_\epsilon \) for \( j \in E_{re}^n \) and \( k \in E_{ce}^n \).

The result is expressed in terms of the following metric on sub-probability measures on \( \mathbb{R} \) via their distribution functions:

\[
D(F, G) \equiv \sum_{i=1}^\infty \left| \int f_i dF - \int f_i dG \right| 2^{-i},
\]

where \( \{f_i\} \) is an enumeration of all continuous functions that take a constant \( \frac{1}{m} \) value (\( m \) a positive integer) on \([a, b]\) where \( a, b \) are rational, \( 0 \) on \(( -\infty, a - \frac{1}{m} ] \cup [ b + \frac{1}{m}, \infty ) \), and linear on each of \([a - \frac{1}{m}, a] \), \([b, b + \frac{1}{m}] \). It is straightforward to verify that \( D(\cdot, \cdot) \) induces the topology of weak convergence on probability measures, and the topology of vague convergence on the set of sub-probability measures. Since for \( x, y \in \mathbb{R} \), \( |f_i(x) - f_i(y)| \leq |x - y| \), we have for two empirical distribution functions (e.d.f.) \( F, G \) on the respective sets \( \{x_1, \ldots, x_n\}, \{y_1, \ldots, y_n\} \)

\[
(1.10) \quad D(F, G) \leq \frac{1}{n} \sum_{j=1}^n |x_j - y_j| \leq \left( \frac{1}{n} \sum_{j=1}^n (x_j - y_j)^2 \right)^{1/2}.
\]

We will prove

**Theorem 1.1.** For each \( \epsilon > 0 \) choose \( d_\epsilon \geq M_\epsilon \) and define \( \widetilde{d}_{jk}^n = \widetilde{d}_{jk}^{n, \epsilon} = d_{jk}^n I(d_{jk}^n \leq d_\epsilon) \). Then with probability one

\[
(1.11) \quad \lim sup_n D(F^B_n, F^0_{n, \epsilon}) \leq \epsilon,
\]

where \( F^0_{n, \epsilon} \) is the probability distribution function having Stieltjes transform

\[
(1.12) \quad G_n(z) = \frac{1}{n} \sum_{i=1}^n \frac{1}{N} \sum_{k=1}^N \frac{1}{1 + \sqrt{\frac{d_{ij}^2}{\epsilon_n^2}(z) - z}},
\]
and for each \( z \in \mathbb{C}^+ \), \( e^0_k = e^0_{n,k}(z) \) are unique solutions lying in \( \mathbb{C}^+ \) to the system of equations

\[
e^0_j(z) = \frac{1}{n} \sum_{i=1}^{n} \frac{\tilde{d}_{ij}^2}{\sum_{k=1}^{N} \frac{d_{nk}^2}{1 + \frac{n}{N} \tilde{\mu}(z) - z}}.
\]

**Corollary 1.2.** With probability one, there exists a (random) sequence \( \{\epsilon_n\} \), such that, with \( d_{ij}^n \) and \( F_{n,\epsilon_n}^0 \) defined as above, we have

\[
\lim_{n \to \infty} D(F_{B_n}, F_{n,\epsilon_n}^0) = 0.
\]

The present assumptions allow for a clearer understanding as to the conditions needed on the entries of \( X_n \) and \( D_n \) separately, so for example, determining the applicability of the theorem on matrix ensembles with the same \( X_n \) satisfying (1.7), (1.8), (1.9) would only require investigating the properties on different \( D_n \)'s. The Lindeberg condition is just assumed on the \( x^{(n)} \)'s, while a tightness-like condition on the \( d_{ij}^n \)'s is only needed. There can be some exceedingly large values of \( d_{ij} \), just not too many of them. The value on the left side of (1.4) can go unbounded.

The conclusion of the Theorem should not be considered substantially weaker than the one in Theorem 10.1 of [Girko 2001]. Typical of eigenvalue results of this nature, it is not known how large the dimension should be in order to obtain prescribed accuracy and reliability. One of the main uses of these limit laws is to be able to identify and understand the underlying assumptions on the makeup of the matrix, typically by viewing a histogram of the random eigenvalues.

The proofs of the Theorem and corollary are given in section 3, following a section on lemmas needed in the proof. Section 3 ends with a scheme to compute \( e^0 \).

2. **Lemmas**

This section contains results on matrix theory and probability need in the proofs.

**Lemma 2.1** ([Horn and Johnson, 1990, Corollary 7.3.8]). For \( r \times s \) matrices \( A \) and \( B \) with respective singular values \( \sigma_1 \geq \cdots \geq \sigma_q \), \( \tau_1 \geq \cdots \geq \tau_q \) where \( q = \min\{r, s\} \), we have

\[
\left( \sum_{i=1}^{q} (\sigma_i - \tau_i)^2 \right)^{1/2} \leq \|A - B\|_2,
\]

where \( \| \cdot \|_2 \) is the Frobenius matrix norm.

Let \( \| \cdot \| \) denote the sup-norm on bounded functions from \( \mathbb{R} \) to \( \mathbb{R} \). It is clear that for probability distribution functions \( F \) and \( G \)

\[
D(F, G) \leq \|F - G\|.
\]

**Lemma 2.2.** For matrices \( A, B \) of the same dimension, \( \text{rank}(A+B) \leq \text{rank}(A) + \text{rank}(B) \).

**Lemma 2.3.** Let \( A \) be \( r \times s \). Then \( \text{rank}(A) \leq \text{number of nonzero rows of } A + \text{the number of nonzero columns of } A \).
Proof. Let \( e_i^* \in \mathbb{R}^n \) be the canonical vector with 1 in the \( i \)-th position and zero in the remaining positions, \( a_j \) the \( j \)-th row of \( A \), and \( a_k \) the \( k \)-th column of \( A \). Then we can write

\[
A = \sum_{j=1}^r e_j a_j = \sum_{k=1}^s a_k e_k^T = \frac{1}{2} \sum_{j=1}^r e_j a_j + \frac{1}{2} \sum_{k=1}^s a_k e_k^T.
\]

Each of the terms in the sums is a rank 1 matrix. Removing all the zero rows and columns and using Lemma 2.2 we get our result. \( \square \)

For Hermitian matrix \( A \) we let \( F^A \) denote the e.d.f. of the eigenvalues of \( A \), and for rectangular matrix \( B \) we let \( F^B_{\text{sing}} \) denote the e.d.f. of the singular values of \( B \).

**Lemma 2.4** ([Bai and Silverstein, 2010, Theorem A.44]). For \( r \times s \) matrices \( A \) and \( B \)

\[
\|F^A - F^B\| \leq \frac{1}{r} \text{rank}(A - B).
\]

Since the rank of a matrix is bounded above by the number of its non-zero rows, we have

**Lemma 2.5.** For matrices in Lemma 2.4

\[
\|F^A - F^B\| \leq \frac{1}{r} \text{number of non-zero rows of } A - B \leq \frac{1}{r} \text{number of non-zero entries of } A - B.
\]

**Lemma 2.6** (Bernstein’s inequality). Let \( X_1, \ldots, X_n \) denote independent mean zero random variables uniformly bounded in absolute value by \( b \), \( S_n = X_1 + \ldots + X_n \) and \( \sigma_n^2 = \text{ES}_n^2 \). Then for any \( \epsilon > 0 \)

\[
P(S_n \geq \epsilon) \leq \exp \left( -\frac{\epsilon^2}{2(\sigma_n^2 + b\epsilon/3)} \right).
\]

**Lemma 2.7** (consequence of Burkholder’s inequality). For \( \{X_k\} \) independent mean-zero random variables we have for any \( p \geq 2 \)

\[
E\left| \sum_k X_k \right|^p \leq C_p \left( \sum_k E|X_k|^p + \left( \sum_k E|X_k|^2 \right)^{p/2} \right).
\]

**Lemma 2.8** ([Bai and Silverstein, 1998]). Let \( \{X_k\} \) be a complex martingale difference sequence. Then, for \( p > 1 \)

\[
E\left| \sum_k X_k \right|^p \leq C_p \left( \sum_k |X_k|^2 \right)^{p/2}.
\]

**Lemma 2.9.** Let \( B, C \) be \( n \times n \) with \( B \) Hermitian, \( x \in \mathbb{C}^n \) and \( z = x + iv \) with \( v > 0 \). Then

\[
\frac{1}{|z(1 + x^*(B - zI)^{-1}x)|} \leq \frac{1}{v} \quad \text{and} \quad \frac{1}{|z(1 + \text{tr} C^*(B - zI)^{-1}C)|} \leq \frac{1}{v}.
\]

Proof. Follows from the fact that the imaginary parts of \( x^*((1/z)B - I)^{-1}x \) and \( \text{tr} C^*((1/z)B - I)^{-1}C \) are both non-negative. \( \square \)
Lemma 2.10 ([Bai and Silverstein, 1998]). Let $z \in \mathbb{C}$ with $v = 3z > 0$, $A, B \in \mathbb{C}^{n \times n}$ with $B$ Hermitian, and $r \in \mathbb{C}^n$. Then

$$|\text{tr}((B - zI)^{-1} - (B + rr^* - zI)^{-1})A| = \left|\frac{r^*(B - zI)^{-1}A(B - zI)^{-1}r}{1 + r^*(B - zI)^{-1}r}\right| \leq \frac{\|A\|_2}{v},$$

where $\|\cdot\|_2$ denotes spectral norm.

Lemma 2.11. For $A, r$ as in Lemma 2.10 with $A$ and $A + rr^*$ both invertible, we have

$$r^*(A + rr^*)^{-1} = \frac{1}{1 + r^*A^{-1}r}r^*A^{-1}.$$  

Proof. Follows from $r^*A^{-1}(A + rr^*) = (1 + r^*A^{-1}r)r^*$.

Lemma 2.12 ([Bai and Silverstein, 2010, Lemma B.26]). Let $A$ be $n \times n$ and $x = (x_1, \ldots, x_n)^T$ where the $x_i$ are independent random variables with $\mathbb{E}x_i = 0$, $\mathbb{E}|x_i|^2 = 1$, and $\mathbb{E}|x_i|\leq \nu_1$. Then for any $p \geq 1$

$$\mathbb{E}|x^*Ax - \text{tr}A|^p \leq C_p \left((\nu_4\text{tr}(AA^*))^{p/2} + \nu_2p\text{tr}(AA^*)^{p/2}\right).$$

Lemma 2.13 ([Horn and Johnson, 1990, Theorem 8.3.1]). Let $\rho(C)$ denote the spectral radius of the $N \times N$ matrix $C$ (the largest of the absolute values of the eigenvalues of $C$). If $C$ contains only nonnegative entries, then $\rho(C)$ is an eigenvalue of $C$ having an eigenvector with nonnegative entries.

Lemma 2.14 ([Horn and Johnson, 1990, Theorem 8.1.18]). Suppose $A = (a_{ij})$ and $B = (b_{ij})$ are $N \times N$ with $b_{ij}$ nonnegative and $|a_{ij}| \leq b_{ij}$. Then

$$\rho(A) \leq \rho((|a_{ij}|)) \leq \rho(B).$$

Lemma 2.15 ([Horn and Johnson, 1991, Lemma 5.7.9]). Let $A = (a_{ij})$ and $B = (b_{ij})$ be $N \times N$ with $a_{ij}, b_{ij}$ nonnegative. Then

$$\rho((\frac{t}{2}b_{11}^2)) \leq (\rho(A))^{\frac{1}{2}}(\rho(B))^{\frac{1}{2}}.$$  

Lemma 2.16 ([Horn and Johnson, 1990, Lemma 5.6.10]). For square $A$ and $\epsilon > 0$ there exists a matrix norm $\|\cdot\|$ such that $\rho(A) \leq \|A\| \leq \rho(A) + \epsilon$.

Lemma 2.17 ([Horn and Johnson, 1990, Theorem 5.6.26]). Let $\|\cdot\|$ be a given matrix norm on $n \times n$ matrices. Then there exists an induced matrix norm $N(\cdot)$ on $n \times n$ matrices such that, for any $n \times n$ matrix $A$ we have $N(A) \leq \|A\|$.

From the last two lemmas, we have

Lemma 2.18. Let $A$ be $n \times n$ satisfy $\rho(A) < 1$. Then there exists a vector norm on $\mathbb{C}^n$, such that with $\|\cdot\|$ denoting its induced matrix norm, we have $\|A\| < 1$.

Lemma 2.19. Let $A$ be an $m \times n$ matrix. Then $\|A\|_2 = \|\text{Adiag}(\omega_1, \ldots, \omega_n)\|_2$, where the $\omega_i$ are numbers on the unit circle in the complex plane.

Proof. Let $y_i \in \mathbb{C}^n$, $i = 1, 2$ be unit vectors for which $\|A\| = \|Ay_1\|_2$ and $\|\text{Adiag}(\omega_1, \ldots, \omega_n)\|_2 = \|\text{Adiag}(\omega_1, \ldots, \omega_n)y_2\|_2$. Then

$$\|A\|_2 \geq \|\text{Adiag}(\omega_1, \ldots, \omega_n)y_2\|_2 = \|\text{Adiag}(\omega_1, \ldots, \omega_n)\|_2 \geq \|\text{Adiag}(\omega_1, \ldots, \omega_n)\text{diag}(\overline{\omega_1}, \ldots, \overline{\omega_n})y_1\|_2 = \|A\|_2,$$

so we get our result.
For sub-probability measures \( \{ \mu_n \} \), \( \mu \), since for fixed \( z \in \mathbb{C}^+ \) the real and imaginary parts of \( 1/(x - z) \) are continuous and approach 0 as \( |x| \to \infty \), we have \( \mu_n \xrightarrow{v} \mu \) (\( v \) denoting vague convergence) implies \( m_{\mu_n}(z) \to m_{\mu}(z) \). Conversely, if \( m_{\mu_n}(z) \) converges for a countably infinite number of \( z \in \mathbb{C}^+ \) possessing a cluster point, all uniformly bounded away from the real axis, from Vitali’s convergence theorem [[Titchmarsh, 1939, p. 168]], \( m_{\mu_n}(z) \) converges for all \( z \) uniformly bounded away from the real axis to an analytic function \( m \). Therefore any vaguely converging subsequence of \( \{ m_n \} \) has their Stieltjes transforms converging to \( m \), and because of the existence of the inverse formula (1.3) we see that \( \mu_n \) converges vaguely to a sub-probability measure \( \mu \) having Stieltjes transform \( m \). Thus we have

**Lemma 2.20.** If for sub-probability measures \( \mu_n \), we have \( m_{\mu_n}(z) \) converging for a countably infinite number of \( z \) uniformly bounded away from the real axis and possessing a cluster point, then there exists a sub-probability measure \( \mu \) for which \( \mu_n \xrightarrow{v} \mu \), or equivalently \( D(\mu_n, \mu) \to 0 \).

**Lemma 2.21** ([Shohat and Tamarkin, 1970, Lemma 2.2]). Let \( f \) be analytic in \( \mathbb{C}^+ \) mapping \( \mathbb{C}^+ \) into \( \mathbb{C}^+ \), and there is a \( \theta \in (0, \pi/2) \) for which \( zf(z) \to c \), finite, as \( z \to \infty \) restricted to \( \{ w \in \mathbb{C}^+ : \theta < \arg w < \pi - \theta \} \). Then \( f \) is the Stieltjes transform of a measure with total mass \( -c \).

**Lemma 2.22** ([Horn and Johnson, 1990, Corollary 8.1.20]). Let \( C N \times N \) have nonnegative entries. Then for each \( i \in \mathbb{C}^+ \) \( \leq \rho(C) \).

**Lemma 2.23** ([Silverstein and Choi, 1995, Theorem 2.1]). Let \( G \) be a probability distribution function and \( x_0 \in \mathbb{R} \). Let \( m_G \) be its Stieltjes transform. Suppose \( \Re m_G(x_0) \equiv \lim_{x \to C^+} \Re m_G(z) \) exists. Then \( G \) is differentiable at \( x_0 \), and its derivative is \( \frac{1}{\pi} \Re m_G(x_0) \).

3. **Proofs of the Theorem and Corollary**

We begin by performing a series of truncations and centralizations on the entries of \( X_n \) and a truncation on the entries of \( D_n \)

Let

\[
\tilde{B}_n = \frac{1}{N}(D_n \circ \bar{X}_n)(D_n \circ \bar{X}_n)^*,
\]

where

\[
\bar{X}_{njk} = x_{jk}^{(n)} I(|x_{jk}^{(n)}| \leq \eta_n \sqrt{n}).
\]

Then from Lemma 2.5

\[
\|F^{B_n} - F^{\tilde{B}_n}\| \leq \frac{1}{n} \sum_{jk} E(|x_{jk}^{(n)}| \geq \eta_n \sqrt{n}).
\]

We have by (1.8)

\[
E\left( \frac{1}{n} \sum_{jk} I(|x_{jk}^{(n)}| \geq \eta_n \sqrt{n}) \right) \leq \frac{1}{\eta_n^2 n^2} \sum_{jk} E|x_{jk}^{(n)}|^2 I(|x_{jk}^{(n)}| \geq \eta_n \sqrt{n}) = o(1),
\]

and

\[
\Var\left( \frac{1}{n} \sum_{jk} I(|x_{jk}^{(n)}| \geq \eta_n \sqrt{n}) \right) \leq \frac{1}{\eta_n^2 n^3} \sum_{jk} E|x_{jk}^{(n)}|^2 I(|x_{jk}^{(n)}| \geq \eta_n \sqrt{n}) = o(1/n).
\]
Therefore, from Lemma 2.6, for arbitrary positive \( \epsilon \) we have for all \( n \) large

\[
P\left( \frac{1}{n} \sum_{jk} I(||x_{jk}^{(n)}|| \geq \eta_n \sqrt{n}) > \epsilon \right) \leq \exp \left( \frac{-(\epsilon - o(1))^2}{2(o(1/n) + (1/n)(\epsilon - o(1)))} \right)
\]

\[
\leq \exp \left( \frac{-n\epsilon^2}{8(1 + \epsilon/3)} \right),
\]

which is summable. Therefore, \( \| F^{B_n} - F^{\tilde{B}_n} \| \xrightarrow{a.s.} 0 \) as \( n \to \infty \).

For fixed \( \epsilon > 0 \), define \( \tilde{d} = d_{\epsilon} \geq M_{\epsilon} \) and \( \tilde{d}_{nk}^n = \tilde{d}_{nk}^{M_{\epsilon}} \) as in the statement of Theorem 1.1, and let \( \tilde{D}_n = (\tilde{d}_{nk}^n) \). From Lemma 2.4 we have

\[
\| F^{\tilde{B}_n} - F^{(1/N)(\tilde{D}_n \circ \tilde{X}_n)(\tilde{D}_n \circ \tilde{X}_n)^*} \| \leq \frac{1}{n} \text{rank}(\tilde{X}_n \circ (D_n - \tilde{D}_n))
\]

The matrix \( \tilde{X}_n \circ (D_n - \tilde{D}_n) \) has at most \#E_{ee}^n \) nonzero rows and \#E_{ce}^n \) columns. Therefore from Lemma 2.3 we have

\[
\| F^{\tilde{B}_n} - F^{(1/N)(\tilde{D}_n \circ \tilde{X}_n)(\tilde{D}_n \circ \tilde{X}_n)^*} \| \leq \epsilon.
\]

By (1.1) and Lemma 2.1 we have

\[
D^2\left( F_{\text{sing}}^{(1/\sqrt{N}) \tilde{D}_n \circ \tilde{X}_n}, F_{\text{sing}}^{(1/\sqrt{N}) \tilde{D}_n \circ (\tilde{X}_n - E \tilde{X}_n)} \right) \leq d^2 \frac{1}{nN} \sum_{jk} |E_{\sigma_{jk}^{(n)}}^{(n)} I(||x_{jk}^{(n)}|| \leq \eta_n \sqrt{n})|^2
\]

\[
= d^2 \frac{1}{nN} \sum_{jk} |E_{\sigma_{jk}^{(n)}}^{(n)} I(||x_{jk}^{(n)}|| > \eta_n \sqrt{n})|^2 \leq d^2 \frac{1}{nN} \sum_{jk} E(||x_{jk}^{(n)}||^2 I(||x_{jk}^{(n)}|| \geq \eta_n \sqrt{n}) \to 0
\]

by (1.8). Since the set of subprobability measures is sequentially compact in vague topology with metric \( D \) and taking square roots of non-negative random variables is a continuous function, we have \( D(F^{\tilde{B}_n}, F^{(1/N)(\tilde{D}_n \circ (\tilde{X}_n - E \tilde{X}_n))(\tilde{D}_n \circ (\tilde{X}_n - E \tilde{X}_n))^*}) \to 0 \) as \( n \to \infty \).

Let

\[
\tilde{X}_n = \left( \frac{x_{jk}^{(n)} I(||x_{jk}^{(n)}|| \leq \eta_n \sqrt{n}) - E(x_{jk}^{(n)} I(||x_{jk}^{(n)}|| \leq \eta_n \sqrt{n}))}{\sigma_{jk}^{(n)}} \right),
\]

where \( \sigma_{jk}^2 = \sigma_{jk}^{2(n)} = E|x_{jk}^{(n)} I(||x_{jk}^{(n)}|| \leq \eta_n \sqrt{n}) - E(x_{jk}^{(n)} I(||x_{jk}^{(n)}|| \leq \eta_n \sqrt{n}))|^2 \) (if \( \sigma_{jk} = 0 \), then define the corresponding entry of \( \tilde{X}_n \) to be zero). Notice that \( \sigma_{jk} \leq 1 \) and, by (1.9), is \( > \sqrt{J} \) for all \( n \) large. Then, again, by (1.1) and Lemma 2.1 we have

\[
D^2\left( F_{\text{sing}}^{(1/\sqrt{N}) \tilde{D}_n \circ \tilde{X}_n}, F_{\text{sing}}^{(1/\sqrt{N}) \tilde{D}_n \circ (\tilde{X}_n - E \tilde{X}_n)} \right) \leq d^2 \frac{1}{nN} \sum_{jk} (1 - \sigma_{jk}^{-1})^2 |x_{jk}^{(n)} I(||x_{jk}^{(n)}|| \leq \eta_n \sqrt{n}) - E(x_{jk}^{(n)} I(||x_{jk}^{(n)}|| \leq \eta_n \sqrt{n}))|^2 \equiv d^2 a(n).
\]
We have

$$Ea(n) = \frac{1}{nN} \sum_{jk} (1 - \sigma_{jk})^2 \leq \frac{1}{nN} \sum_{jk} (1 - \sigma_{jk}^2)$$

$$= \frac{1}{nN} \sum_{jk} E|x_{jk}^{(n)}|^2 I(|x_{jk}^{(n)}| > \eta_n \sqrt{n}) + E x_{jk}^{(n)} I(|x_{jk}^{(n)}| > \eta_n \sqrt{n})^2$$

$$\leq \frac{2}{nN} \sum_{jk} E|x_{jk}^{(n)}|^2 I(|x_{jk}^{(n)}| \geq \eta_n \sqrt{n}) \to 0,$$

as \( n \to \infty \), by (2.1).

Let \( a_{jk} = |x_{jk}^{(n)} I(|x_{jk}^{(n)}| \leq \eta_n \sqrt{n}) - E(x_{jk}^{(n)} I(|x_{jk}^{(n)}| \leq \eta_n \sqrt{n}))|^2 \). Using Lemma 2.7 and (1.9) for all \( n \) large we have

$$E|a(n) - Ea(n)|^4 \leq \frac{C_4}{(nN)^4} \left( \sum_{jk} (1 - \sigma_{jk}^{-1})^8 E|a_{jk} - Ea_{jk}|^4 + \left( \sum_{jk} (1 - \sigma_{jk}^{-1})^4 E|a_{jk} - Ea_{jk}|^2 \right)^2 \right)$$

$$\leq \frac{C'}{n^8} \left( \sum_{jk} E|x_{jk}^{(n)}|^4 I(|x_{jk}^{(n)}| \leq \eta_n \sqrt{n}) + \left( \sum_{jk} E|x_{jk}^{(n)}|^2 I(|x_{jk}^{(n)}| \leq \eta_n \sqrt{n}) \right)^2 \right)$$

$$\leq \frac{C''}{n^8} (n^5 \eta_n^6 + n^6 \eta_n^4),$$

which is summable.

Therefore, we conclude that

$$\limsup_n D(F^{B_n}, F^{(1/\sqrt{N})(D_n \circ X_n)(D_n \circ X_n)^*}) \leq \epsilon \quad \text{a.s.}$$

From this point, for ease of notation, we will denote the augmented matrix also by \( B_n = (1/\sqrt{N})(D_n \circ X_n)(D_n \circ X_n)^* \), where we will assume that \( x_{jk}^{(n)} \), the entries of \( X_n \) satisfy

1. For each \( n \) they are independent.
2. \( E(x_{jk}^{(n)}) = 0, E|x_{jk}^{(n)}|^2 = 1. \)
3. \( |x_{jk}^{(n)}| \leq \eta_n \sqrt{n}, \)

where the present \( \eta_n \) are double the original \( \eta_n \),

and that the elements of \( D_n \) are nonnegative and bounded by \( d = d_\epsilon \). Keep in mind the difference between the two \( B_n \)'s, along with the bound (3.1).

Let \( x_k \) denote the \( k \)-th column of \( X_n \). Let \( D_k \) denote the \( n \times n \) diagonal matrix consisting of the entries in the \( k \)-th column of \( D_n \). Then we can write

$$B_n = \frac{1}{N} \sum_{k \leq N} D_k x_k x_k^* D_k.$$

Let \( E_\sigma(\cdot) \) denote expectation and \( E_\xi(\cdot) \) denote conditional expectation with respect to the \( \sigma \)-field generated by \( x_1, \ldots, x_k \). Let for \( k \leq N \)

$$B_{(k)} = \frac{1}{N} \sum_{j \neq k} D_j x_j x_j^* D_j.$$
Taking inverses and using Lemma 2.11 we get
which is summable. Therefore we have (3.2).

Let $m_1 = 10$. By Lemma 2.10 we have each

We have

The first step is to show

Taking the trace, and dividing by $n$, we get

Write

We turn to

By Lemma 2.10 we have each $|x| \leq 2/4$. Since the $\xi_k$ form a martingale difference sequence, we have by Lemma 2.8:

The first step is to show

We have

Let $m_1(z) = x + i y$, $v > 0$ denote the Stieltjes transform of the eigenvalues of
where
\[
\alpha_k = \frac{1}{n} x_k^* D_k (B_k - z I)^{-1} (F - z I)^{-1} D_k x_k \\
\beta_k = \frac{1}{n} x_k^* D_k (B_k - z I)^{-1} (F - z I)^{-1} D_k x_k \\
\gamma_k = \frac{1}{n} \text{tr} D_k (B_k - z I)^{-1} (F - z I)^{-1} D_k,
\]
and
\[
\gamma_k = \frac{1}{n} \text{tr} D_k (B_k - z I)^{-1} (F - z I)^{-1} D_k \\
\beta_k = \frac{1}{n} x_k^* D_k (B_k - z I)^{-1} (F - z I)^{-1} D_k x_k \\
\gamma_k = \frac{1}{n} \text{tr} D_k (B_k - z I)^{-1} (F - z I)^{-1} D_k.
\]

Notice that the spectral norms of \((B_n - z)^{-1}\) and \((B_k - z I)^{-1}\) are bounded by \(1/v\). Also notice that \(\exists \epsilon_k > 0\) so that \(\exists F < 0\). This implies \(||(F - z I)^{-1}|| < 1/v\).

We have \(E \beta_k = 0\). From Lemmas 2.9 and 2.10 we have
\[
|\gamma_k| \leq \frac{1}{n} \frac{d^2 |z|}{v^3} \to 0.
\]
as \(n \to \infty\).

From Lemmas 2.9, 2.12, and the Cauchy-Schwarz inequality we have
\[
|\epsilon_k| \leq \frac{n |z|^2}{N v^2} \left((1/n^2) |x_k^* D_k (B_k - z I)^{-1} (F - z I)^{-1} D_k x_k|^2\right)^{1/2}
\]
\[
\left((1/n^2) (|x_k^* D_k (B_k - z I)^{-1} D_k x_k - E \text{tr} D_k (B_k - z I)^{-1} D_k|^2\right)^{1/2}.
\]

We have
\[
(3.4) \quad (1/n^2) E |x_k^* D_k (B_k - z I)^{-1} (F - z I)^{-1} D_k x_k|^2 \leq \frac{d^4}{v^4 n^2} E \|x_k\|^4
\]
\[
= \frac{d^4}{v^4 n^2} \left(\sum_{j=1}^n E |x_{jk}|^4 + n(n - 1)\right) \leq \frac{d^4}{v^4 n^2} (\eta_n^2 n^2 + n(n - 1)) = O(1)
\]

We have
\[
(1/n^2) (|x_k^* D_k (B_k - z I)^{-1} D_k x_k - E \text{tr} D_k (B_k - z I)^{-1} D_k|^2
\]
\[
\leq (2/n^2) (|x_k^* D_k (B_k - z I)^{-1} D_k x_k - E \text{tr} D_k (B_k - z I)^{-1} D_k|^2
\]
\[
+ (2/n^2) E \|D_k (B_k - z I)^{-1} D_k - E \text{tr} D_k (B_k - z I)^{-1} D_k|^2.
\]

Using Lemma 2.12 we have
\[
(3.5) \quad (1/n^2) (|x_k^* D_k (B_k - z I)^{-1} D_k x_k - E \text{tr} D_k (B_k - z I)^{-1} D_k|^2
\]
\[
\leq (C/n^2) (\eta_n^2 n) E \|D_k (B_k - z I)^{-1} D_k - E \text{tr} D_k (B_k - z I)^{-1} D_k\| \leq C \eta_n^2 \to 0
\]
as \(n \to \infty\). As before, we can write \((1/n)(\text{tr} D_k (B_k - z I)^{-1} D_k - E \text{tr} D_k (B_k - z I)^{-1} D_k)\) as a sum of martingale differences, where now each term is bounded in absolute value by \(2d^2/v\). Using Lemma 2.8 we find then that
\[
(1/n^2) E |\text{tr} D_k (B_k - z I)^{-1} D_k - E \text{tr} D_k (B_k - z I)^{-1} D_k|^2 = O(1/n).
\]
We conclude that
\[ \mathbb{E}m_n(z) - (1/n)\text{tr} (F - zI)^{-1} \to 0, \]
as \( n \to \infty. \)

In (3.3), multiply both sides on the left and right by \( D_j \). Taking the trace and dividing by \( n \) we get
\[
\frac{1}{n} \text{tr} D_j(F - zI)^{-1} D_j - \frac{1}{n} \text{tr} D_j(B_n - zI)^{-1} D_j
\]
\[ = \frac{1}{N} \sum_{k=1}^{N} \left[ \frac{1}{n} x_k^* D_k(B_k - zI)^{-1} D_k^2 (F - zI)^{-1} D_k x_k}{1 + \frac{n}{N} x_k^* D_k(B_k - zI)^{-1} D_k x_k} \right].
\]
In approaching this sum in the same way as before we can conclude that
\[ \mathbb{E}(1/n)D_j(B_n - zI)^{-1} D_j - (1/n)\text{tr} D_j(F - zI)^{-1} D_j \to 0 \]
as \( n \to \infty. \) Using Lemma 2.10 we have
\[ e_j(z) - (1/n)\text{tr} D_j(F - zI)^{-1} D_j \to 0 \]
as \( n \to \infty. \)

Thus we have, expressed in terms of the entries of \( D_n \)
\[ m_n(z) - \frac{1}{n} \sum_{i=1}^{n} \frac{1}{N} \sum_{k=1}^{N} \frac{d_{ik}^2}{1 + \frac{n}{N} e_k(z)} - z \]
a.s. as \( n \to \infty, \) where the \( e_j(z) \) satisfy
\[ e_j(z) - \frac{1}{n} \sum_{i=1}^{n} \frac{d_{ij}^2}{1 + \frac{n}{N} e_k(z)} - z \]
as \( n \to \infty. \)

We shall prove that for fixed \( n \) and \( N \) there exist \( e^0_1(z), \ldots, e^0_N(z) \in \mathbb{C}^+ \) that satisfies (1.6). Consider the matrix \( B_{n\ell} = (1/(N\ell))(D^{(\ell)} \circ X^{(\ell)})(D^{(\ell)} \circ X^{(\ell)})^* \) where \( X^{(\ell)} \) is now \( n\ell \times N\ell \) containing i.i.d bounded standardized variables, and \( D^{(\ell)} \) is \( n\ell \times N\ell \) containing \( \ell^2 \) copies of \( D_n \). Then (3.7) holds a.s. as \( \ell \to \infty. \) Notice that for any positive integer \( k \leq N \) columns \( k, N + k, \ldots, (\ell - 1)N + k \) of \( D^{(\ell)} \) are identical. Using Lemma 2.10 we see that
\[ |e_{m_1N+k}(z) - e_{m_2N+k}(z)| \leq \frac{2d^2}{n\ell v} \quad 0 \leq m_1, m_2 \leq \ell - 1. \]

Consider one realization for which (3.7) holds. Since the \( e_k(z) \)’s are bounded by \( d^2/v \), we can find a subsequence of \( \{\ell\} \) such that \( e_1(z), \ldots, e_N(z) \) converge to \( e^0_1(z), \ldots, e^0_N(z) \) on this subsequence. We have then for \( 1 \leq i \leq n\ell \)
\[ \frac{1}{N\ell} \sum_{k=1}^{N\ell} \frac{d_{ik}^{(\ell)}2}{1 + \frac{n}{N} e_k(z)} \]
\[ = \frac{1}{N} \sum_{k=1}^{N} \frac{1}{\ell} \sum_{m=1}^{\ell} \frac{d_{ik}^2}{1 + \frac{n}{N} e_{mN+k}(z)} \to \frac{1}{N} \sum_{k=1}^{N} \frac{1}{1 + \frac{n}{N} e_k^0(z)} \]
on this subsequence. Since the \( e_k(z) \) have positive imaginary part, the above limit has nonpositive imaginary part. Therefore the right side of (1.6) has positive imaginary part.
Fix $j \leq N$. Using the fact that the $d_{ij}^{(\ell)}$s repeat as $i$ ranges from 1 to $n\ell$, from (3.7) we get

$$e_j(z) - \frac{1}{n\ell} \sum_{i=1}^{n\ell} \frac{d_{ij}^{(\ell)}2}{\frac{1}{N} \sum_{k=1}^{N\ell} d_{ik}^{(j)} + |e_k(z)|} = e_j(z) - \frac{1}{n} \sum_{i=1}^{n} \frac{d_{ij}^2}{\frac{1}{N} \sum_{k=1}^{N\ell} d_{ik}^{(j)} + |e_k(z)|} \to 0,$$

so we get (1.6) with each $e_j(z) \in \mathbb{C}_+$. We will now show the uniqueness of the $e_k^0(z)$ in (1.6) having positive imaginary parts. Notice that from (1.6) the $e_k^0(z)$ are also bounded in absolute value by $d^2/v$.

Let $e_{j,2}^0(z)$ denote the imaginary part of $e_j^0(z)$. Then

$$e_{j,2}^0(z) = \frac{1}{n} \sum_{i=1}^{n} d_{ij}^2 \frac{1}{\frac{1}{N} \sum_{k=1}^{N\ell} d_{ik}^2 + |e_k(z)|^2} \cdot (\frac{1}{v} e_{j,2}^0(z) + v),$$

Let $C^0 = \{ e_{j,k}^0 \} N \times N$ and $b^0 = (b_{1,1}^0, \ldots, b_{N,1}^0)^T$, where

$$e_{j,k}^0 = \frac{1}{N^2} \sum_{i=1}^{n} d_{ij}^2 d_{ik}^2 \frac{1}{\frac{1}{N} \sum_{k=1}^{N\ell} d_{ik}^2 + |e_k(z)|^2} \cdot (\frac{1}{v} e_{j,k}^0(z) + v),$$

and

$$b_j^0 = \frac{1}{n} \sum_{i=1}^{n} d_{ij}^2 \frac{1}{\frac{1}{N} \sum_{k=1}^{N\ell} d_{ik}^2 + |e_k(z)|^2} \cdot (\frac{1}{v} e_{j,k}^0(z) + v).$$

Let $e_2^0 = (e_{1,2}^0(z), \ldots, e_{N,2}^0(z))^T$. Then

$$e_2^0 = C^0 e_2^0 + vb^0.$$

Notice because of the nonzero assumption on any column of $D_n$, equation (3.8) has all components of $e_2^0(z)$ and $b^0$ positive.

Suppose $\rho(C^0)$, the spectral radius of $C^0$, is greater than or equal to 1. Then by Lemma 2.13 $\rho(C^0)$ is an eigenvalue of $C^0$ with left eigenvector $y^T$ containing nonnegative entries, and necessarily, at least one entry is positive. Multiplying on the left of both sides of (3.8) by $y^T$ we get

$$y^T e_2^0 = \rho(C^0) y^T e_2^0 + vy^T b^0.$$

Since both $y^T e_2^0$ and $y^T b^0$ are positive, we arrive at a contradiction. Therefore

$$\rho(C^0) < 1.$$

Suppose $e_j^0(z), \ldots, e_j^0(z)$ also satisfy (1.6). Let $\bar{e}_j^0$ and $\bar{C}_j^0 = \{ \bar{e}_{j,k}^0 \}$ denote the quantities analogous to $e_j^0$ and $C^0$. Then for nonzero $\bar{e}_j^0(z)$ and $\bar{e}_j^0(z)$ we have

$$e_j^0 - \bar{e}_j^0 = \sum_{k=1}^{N} a_{jk}(e_k^0(z) - \bar{e}_k^0(z)),$$
where

\[(3.11)\quad a_{jk} = \frac{1}{N^2 (1 + \frac{n}{N} e^0_k(z))(1 + \frac{n}{N} e^0_k(z))} \times \sum_{i=1}^{n} \left( \frac{1}{N} \sum_{k=1}^{N} \frac{d_{ik}^2 d_{jk}^2}{1 + \frac{n}{N} e^0_k(z)} \right). \]

Therefore, with \(e^0 = (e^0_1(z), \ldots, e^0_N(z))^T\) and \(\mathbf{c}^0 = (e^0_1(z), \ldots, e^0_N(z))^T\) we have

\[(3.12)\quad e^0 - c^0 = A(e^0 - c^0), \]

where \(A = (a_{jk})\). If \(e^0 \neq c^0\) then \(A\) has an eigenvalue equal to 1. However applying Cauchy-Schwarz we see that

\[|a_{jk}| \leq c^0_j c^0_k \mathcal{N}^{1/2}, \]

and applying Lemmas 2.14 and 2.15

\[\rho(A) \leq \rho(c^0_j c^0_k \mathcal{N}^{1/2}) \leq (\rho(c^0_j c^0_k))^{1/2} < 1, \]

by (3.10), a contradiction. Therefore we have \(e^0 = c^0\).

Using the last part of the above argument, we will show that \(e^0(z)\) is a continuous function of \(z \in \mathbb{C}^+\). Let \(\{z_n\}\) and \(\{z'_n\}\) be two sequences in \(\mathbb{C}^+\) each converging to \(z \in \mathbb{C}^+\). Let \(e^0(z) = (e^0_1(z), \ldots, e^0_N(z))^T\). Then \(e^0(z_n)\) and \(e^0(z'_n)\) satisfy

\[(3.13)\quad e^0(z_n) - e^0(z'_n) = A(z_n, z'_n)(e^0(z_n) - e^0(z'_n)) + (z_n - z'_n)b(z_n, z'_n), \]

where

\[A(z_n, z'_n)_{jk} = \frac{1}{N^2 (1 + \frac{n}{N} e^0_k(z_n))(1 + \frac{n}{N} e^0_k(z'_n))} \times \sum_{i=1}^{n} \left( \frac{1}{N} \sum_{k=1}^{N} \frac{d_{ik}^2 d_{jk}^2}{1 + \frac{n}{N} e^0_k(z_n)} \right) \]

and

\[b(z_n, z'_n)_{ij} = \frac{1}{n} \sum_{i=1}^{n} \left( \frac{1}{N} \sum_{k=1}^{N} \frac{d_{ik}^2}{1 + \frac{n}{N} e^0_k(z_n)} \right) \left( \frac{1}{N} \sum_{k=1}^{N} \frac{d_{ik}^2}{1 + \frac{n}{N} e^0_k(z'_n)} \right). \]

Assume \(e^0(z_n) \to e^0\) and \(e^0(z'_n) \to e^0\) as \(n \to \infty\). Since all quantities are bounded we get as \(n \to \infty\) (3.12), and therefore \(e^0 = c^0\), which proves continuity of \(e^0(z)\), \(z \in \mathbb{C}^+\).

We claim that each \(e_k(z)\) is the Stieltjes transform of a measure with total mass \((1/n)\text{tr}D_k^2\). Indeed, for all \(z\) with imaginary part \(\geq v > 0\) any difference quotient

\[\frac{1}{n} \text{tr} D_k(B_k(z_1I) - z_1I)^{-1}D_k - \frac{1}{n} \text{tr} D_k(B_k(z_2I) - z_2I)^{-1}D_k \]

is uniformly bounded. Therefore, by the dominated convergence theorem \(e_k\) is differentiable for all \(z \in \mathbb{C}^+\), and hence is analytic on \(\mathbb{C}^+\). Moreover it is clear that
$e_k$ maps $\mathbb{C}^+$ into $\mathbb{C}^+$ and, again by the dominated convergence theorem, the limit of $ze_k(z)$ as $z \to \infty$ is $-(1/n)\text{tr} D_k^2$. Therefore by Lemma 2.21 the claim is proven.

Now, since, from the above existence argument, for each $n$, $e_k^0$ is the limit of a sequence of $e_k$’s we have, using the Helly selection theorem, $e_k^0$ is itself the Stieltjes transform of a measure with total mass $(1/n)\text{tr} D_k^2$. Therefore the function $G_n(z)$ is analytic in $\mathbb{C}^+$, maps $\mathbb{C}^+$ to $\mathbb{C}^+$, and as $z \to \infty$, $zG_n(z) \to -1$. Therefore, by Lemma 2.21 $G_n(z)$ is the Stieltjes transform of a probability measure, $P_n^0$, on $\mathbb{R}$.

We will proceed to show that the $e_k(z)$ in (3.6) can be replaced with the $e_k^0(z)$, that is, we will show that

$$m_n(z) - G_n(z) = m_n(z) - \frac{1}{n} \sum_{i=1}^{n} \frac{1}{1 + \frac{1}{N} \sum_{k=1}^{N} d_{ik}^2} \to 0$$

almost surely. We have

$$\frac{1}{n} \sum_{i=1}^{n} \frac{1}{1 + \frac{1}{N} \sum_{k=1}^{N} d_{ik}^2} - \frac{1}{n} \sum_{i=1}^{n} \frac{1}{1 + \frac{1}{N} \sum_{k=1}^{N} d_{ik}^2} - z = \frac{1}{N^2} \sum_{k=1}^{N} \frac{(e_k(z) - e_k^0(z))}{(1 + \frac{1}{N} e_k(z))(1 + \frac{1}{N} e_k^0(z))}$$

$$\times \sum_{i=1}^{n} \left( \frac{1}{N} \sum_{k=1}^{N} \frac{d_{ik}^2}{1 + \frac{1}{N} e_k(z)} - z \right) \left( \frac{1}{N} \sum_{k=1}^{N} \frac{d_{ik}^2}{1 + \frac{1}{N} e_k^0(z)} - z \right).$$

Returning now to $C^0$, $b^0$, and $e_k^0$, we see that the entries of $b^0$ are uniformly bounded. Let $1_m$ denote the $m$ dimensional vector containing all one’s, and let “≤” between two vectors denote entry wise ≤. Using Lemma 2.9 we see that

$$(3.16)\quad C^0 1_N \leq \left( \frac{n}{N} \frac{|z|^2}{v^2} \max_i \frac{1}{N} \sum_{k=1}^{N} d_{ik}^2 \right) b^0. $$

Since the entries of $e_k^0$ are uniformly bounded we see from (3.8) that

$$(3.17)\quad e_2^0 \leq k_1 b^0.$$

From (3.9), where $y$ is the nonnegative eigenvector of $C^0$ associated with $\rho(C^0)$ we get

$$(3.18)\quad 1 - \rho(C^0) = \frac{vy^T b^0}{y^T e_2^0} \geq k,$$

where necessarily $k \in (0, 1)$. Let $\omega \in \mathbb{R}^n$ have for its $j$-th entry the imaginary part of the lefthand side of (3.7). From condition (1.9) we see that $\eta_n$ approaches zero more slowly than $1/n$. Thus, from the derivation of (3.7) it is clear that

$$(3.19)\quad |\omega| \leq k_1 \eta_n 1_N.$$

Let $e_{j,2}(z)$ denote the imaginary part of $e_j(z)$ and $e_2 = (e_{1,2}, \ldots, e_{N,2})^T$. Similar to $C^0$ and $b^0$ we have

$$(3.20)\quad e_2 = C e_2 + vb + \omega,$$
where
\[ c_{jk} = \frac{1}{N^2} \sum_{i=1}^{n} d_{ij}^2 d_{ik}^2 \frac{n_{1+\frac{n}{N} e_{1}(z)}^2}{n_{1+\frac{n}{N} e_{1}(z)} - z}^2 \]
and
\[ b_j = \frac{1}{n} \sum_{i=1}^{n} d_{ij}^2 \frac{n_{1+\frac{n}{N} e_{1}(z)} - z}^2. \]

We will show
\[ \limsup_{n \to \infty} \rho(C) \leq 1. \]

Rather than work with \( C \) we consider \( C_s \equiv E^{-1}CE \) where \( E = \text{diag}(1 + \frac{n}{N} e_{1}(z), \ldots, 1 + \frac{n}{N} e_{N}(z)) \). Notice \( C_s \) is a symmetric matrix and its eigenvalues are the same as \( C \). From Lemma 1.7 and the fact that \(|1+\frac{n}{N} e_{1}(z)| \leq 1 + \frac{1}{N^2} \sum_{i=1}^{n} d_{ij}^2 \), we see that the diagonal entries of \( E \) and \( E^{-1} \) are uniformly bounded. Let \( f = E^{-1} e_2 \), \( b = E^{-1} v_b \), and \( \omega = E^{-1} \omega \). Then from (3.20) we have
\[ f = C_s f + b + \omega. \]

We have the entries of \( b \) uniformly bounded,
\[ |\omega| \leq k_2 \eta_1 1_N \]
and, similar to (3.16), we have
\[ C_s 1_N \leq k_3 b. \]

Consider those entries of \( f_j \) for which \( b_j + \omega_j > 0 \) and those entries for which \( b_j + \omega_j \) are negative. Rearrange the coordinates so that the first \( \ell \) entries satisfy the former, the remaining the latter and put \( C_s \) into corresponding block form:
\[ C_s = \begin{pmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{pmatrix}. \]

Splitting \( f, b \) and \( \omega \) into appropriate parts we have
\[ f_1 = C_{11} f_1 + C_{12} + b_1 + \omega_1 \]
\[ f_2 = C_{21} f_1 + C_{22} f_2 + b_2 + \omega_2, \]
where \( f = (f_1^T, f_2^T)^T \), etc. Applying the left nonnegative eigenvector of \( C_{11} \) corresponding to \( \rho(C_{11}) \) to both sides of (3.24) we see that \( \rho(C_{11}) < 1 \). There exists \( k_4 \) for which
\[ C_{11} 1_\ell \leq k_4 1_\ell, \quad C_{12} 1_{N-\ell} \leq k_4 1_\ell, \quad b_2 \leq k_4 \eta_1 1_{N-\ell}, \quad C_{21} 1_\ell \leq k_4 \eta_1 1_{N-\ell}, \quad \text{and} \quad C_{22} 1_{N-\ell} \leq k_4 \eta_1 1_{N-\ell}. \]

From Lemma 1.17 we see that \( \rho(C_{22}) \leq k_4 \eta_n \), which is less than \( 1/2 \) for all \( n \) large. Notice then for these \( n \) (which we assume we consider from this point on) that if \( \ell = 0 \) or \( N \) then \( \rho(C) = \rho(C_s) < 1 \) and we would be done. So we assume \( 1 < \ell < N \).

Let \( x = (x_1^T, x_2^T)^T \) be a nonnegative eigenvector of \( C_s \) corresponding to \( \rho(C_s) \). Then we have
\[ \rho(C_s) x_1 = C_{11} x_1 + C_{12} x_2 \]
\[ \rho(C_s) x_2 = C_{21} x_1 + C_{22} x_2. \]
When \( \rho(C_s) > 1 \) we have \( \rho(C_s)I - C_{22} \) invertible (smallest eigenvalue \( \geq 1/2 \) and \( \| (\rho(C_s)I - C_{22})^{-1} \| \leq 2 \). From the second identity we have \( x_2 = (\rho(C_s) - C_{22})^{-1}C_{21}x_1 \) and plugging this into the first we find

\[
(3.27) \quad \rho(C_s)x_1 = (C_{11} + C_{12}(\rho(C_s)I - C_{22})^{-1}C_{21})x_1.
\]

We have when \( \rho(C_s) \geq 1 \)

\[
(\rho(C_s)I - C_{22})^{-1}1_N = \frac{1}{\rho(C_s)} \sum_{m=0}^{\infty} \frac{C_{22}^m}{\rho(C_s)^m} 1_N
\]

\[
\leq \frac{1}{\rho(C_s)} \sum_{m=1}^{\infty} \frac{1}{(2\rho(C_s))^m} 1_N = \frac{1}{\rho(C_s)} \frac{1}{1 - 1/(2\rho(C_s))} 1_N = \frac{1}{\rho(C_s)} \frac{1}{1 - \frac{1}{2}} 1_N.
\]

From (3.26) we have

\[
C_{12}(\rho(C_s)I - C_{22})^{-1}C_{21}1_\ell \leq \frac{\eta_n k_4^2}{\rho(C_s) - \frac{1}{2}} 1_\ell.
\]

Therefore, for all \( n \) large, when \( \rho(C_s) \geq 1 \)

\[
(3.28) \quad \rho(C_{12}(\rho(C_s)I - C_{22})^{-1}C_{21}) = \| C_{12}(\rho(C_s)I - C_{22})^{-1}C_{21} \|_2 \leq k_5 \eta_n
\]

If \( x_1 = 0 \), then \( \rho(C_s) = \rho(C_{22}) \leq 1/2 \). Therefore, when \( \rho(C_s) \geq 1 \) we have \( x_1 \neq 0 \) and so applying the spectral norm on (3.27) we have

\[
\rho(C_s) \leq \rho(C_{11}) + k_5 \eta_n,
\]

and so (3.21) holds.

Let \( e = (e_1(z), \ldots, e_N(z))^T \). Let now \( \omega \in \mathbb{C}^n \) have for its entries the lefthand side of (3.7). We may assume

\[
|\omega| \leq k_4 \eta_n 1_N.
\]

From (1.6) and (3.7), we have

\[
e - e^0 = A(e - e^0) + \omega,
\]

where \( A = (a_{jk}) \) with

\[
a_{jk} = \frac{1}{N^2} \frac{1}{1 + \frac{1}{N} e_k(z)} \frac{d_z^2}{d_{ik} d_{jk}} \left( \frac{1}{N} \sum_{k=1}^{N} \frac{d_z^2}{d_{ik} d_{jk}} - z \right) \left( \frac{1}{N} \sum_{k=1}^{N} \frac{d_z^2}{d_{ik} d_{jk}} - z \right).
\]

Using the same arguments seen earlier, we have from (3.18), (3.21) for all \( n \) large the existence of a \( k_6 \in (0, 1) \) such that

\[
\rho(A) \leq k_6.
\]

Therefore \( I-A \) is invertible and we get

\[
(3.30) \quad e - e^0 = (I - A)^{-1} \omega.
\]
Let $D_2 = D_n \circ D_n$, $F^0 = \text{diag}(1 + \frac{2}{N} e_1^0(z), \ldots, 1 + \frac{2}{N} e_N^0(z))$, $F = \text{diag}(1 + \frac{2}{N} e_1(z), \ldots, 1 + \frac{2}{N} e_N(z))$.

$$G^0 = \text{diag} \left( \frac{1}{N} \sum_{k=1}^{N} \frac{d^2_{ik}}{1 + \sum_{j=1}^{N} e_j(z)} - z \right), \ldots, \frac{1}{N} \sum_{k=1}^{N} \frac{d^2_{nk}}{1 + \sum_{j=1}^{N} e_j(z)} - z \right)$$

and

$$G = \text{diag} \left( \frac{1}{N} \sum_{k=1}^{N} \frac{d^2_{ik}}{1 + \sum_{j=1}^{N} e_j(z)} - z \right), \ldots, \frac{1}{N} \sum_{k=1}^{N} \frac{d^2_{nk}}{1 + \sum_{j=1}^{N} e_j(z)} - z \right)$$

Then we can write $A = \frac{1}{N^2} D_2^T G G^0 D_2 F^{0-1} F^{-1}$. Writing $F^{-1} = E^{-1} \text{diag}(\omega_1, \ldots, \omega_N)$ where the $\omega_i$’s are on the unit circle in the complex plane, we see that since $\{(1/N)GD_2 E^{-1}\}^*(1/N)GD_2 E^{-1} = C$, we have from Lemma 2.19 $\|(1/N)GD_2 F^{-1}\|_2 = \rho^{1/2}(C)$. Similarly we have $\|(1/N)G^0 D_2 F^{0-1}\|_2 = \rho^{1/2}(C^0)$. Therefore, for all $n$ large we have $k_7 \in (0, 1)$ such that

$$\|(F^{-1}AF)\|_2 \leq \|(1/N)GD_2 F^{-1}\|_2 \|(1/N)G^0 D_2 F^{0-1}\|_2 < k_7,$$

and so $(I - F^{-1}AF)^{-1}$ exists and is bounded in spectral norm for all $n$ large. Therefore, using the fact that $F$ is bounded in spectral norm we have

$$e - e^0 = F(I - F^{-1}AF)^{-1}F^{-1} = H \omega,$$

where $H$ is bounded in spectral norm for all $n$ large.

We have then (3.15) $\frac{1}{N^2} \text{diag}(\omega_1, \ldots, \omega_N)$ uniformly bounded away from the real axis having a cluster point. For any $\omega \in A$, and any vaguely converging subsequence of $F^{B_n}$, say to $F_\mu$ with $\mu$ a sub-probability measure, we have $m_{n_j}(z) \to \mu(z) \equiv \int \frac{1}{z - w} dF_\mu$, $z \in \{z_m\}$. Necessarily $H_\mu(z) \to \mu(z)$, $z \in \{z_m\}$. By Lemma 2.20 we have $F^0_{n_j}$ converging vaguely to the distribution function of a measure, which, because of uniqueness of measures and their Stieltjes transforms, must necessarily be $\mu$. Thus, $D(F^{B_{n_j}}, F^0_{n_j}) \to 0$ on this subsequence. Since by the Helly selection theorem for an arbitrary subsequence, there exists a further subsequence for which vague convergence holds, we must have

$$D(F^{B_n}, F^0_n) \to 0, \quad \omega \in A.$$ Combining this result with (3.1) we have for any $\epsilon > 0$ with probability one

$$\limsup_n D(F^{B_n}, F^0_{n,\epsilon}) \leq \epsilon.$$
where $B_n$ is now the original matrix defined in (1.1) and $F_{n,\epsilon}$ is the distribution function of the probability measure having Stieltjes transform $G_{n,\epsilon}$, which is $G_n$ defined in terms of the truncated $d_{jk}^n$'s, namely $d_{jk}^n I(d_{jk}^n \leq \epsilon)$ with $\epsilon \geq M_n$.

For the proof of the corollary, we let $A$ be a set of probability one for which for each $\omega \in A$
\[
\limsup_n D(F_{n,1/m}) \leq 1/m, \quad m = 1, 2, \ldots.
\]
For fixed $\omega \in A$, choose integers $N_2 > N_1 > 0$ arbitrarily. Choose integer $N_3 > N_2$ for which $D(F_{n,1/3}) \leq 2/3$ for all $n \geq N_3$, and recursively choose $N_m > N_{m-1}$ for which $D(F_{n,1/m}) \leq 2/m$ for all $n \geq N_m$. We thus have the existence of \{\epsilon_n\}, such that $D(F_{n,\epsilon_n}) \to 0$, an event which occurs with probability one.

We conclude with a way to compute $e^0$ associated with $D_n = (d_{ij})$. We will show that there exists a neighborhood of $e^0$ for which the scheme
\[
(3.31) \quad e^{\ell+1}_j = \frac{1}{n} \sum_{i=1}^n \frac{d_{ij}^2}{\sum_{k=1}^N d_{kj}^2 (\epsilon_j)} - z.
\]
converges to $e^0$. Consider the matrix $A$ in (3.12) with $e^0$ replaced by $e$ and denote it by $A(e)$. Then we have $\rho(A(e^0)) < 1$. By Lemma 2.18 we can find a vector norm $\| \cdot \|$ where its induced matrix norm $\| \cdot \|$ satisfies $\|A(e^0)\| \leq \alpha < 1$ for some $\alpha$.

Then, for a given $\beta \in (\alpha, 1)$, by continuity we can find a $\| \cdot \|$ open ball $\mathbb{B}$ of $e^0$ such that $\|A(e)\| \leq \beta$ for all $e \in \mathbb{B}$. Therefore, writing $e^\ell = (e_1^\ell(z), \ldots, e_N^\ell(z))^T$, $e^{\ell+1} = (e_1^{\ell+1}(z), \ldots, e_N^{\ell+1}(z))^T$, if $e^\ell \in \mathbb{B}$ we have
\[
e^0 - e^{\ell+1} = A(e^\ell)(e^0 - e^\ell),
\]
and
\[
\|e^0 - e^{\ell+1}\| \leq \|A(e^\ell)\| \|e^0 - e^\ell\| \leq \beta \|e^0 - e^\ell\|.
\]
Therefore $e^{\ell+1} \in \mathbb{B}$ and we get convergence to $e^0$.

**Acknowledgement.** Special thanks go to Zhidong Bai for his aid in deciding on the tightness-like condition on the entries of $D_n$.
